The roots

Scientometrics, as an inter-disciplinary field, has its roots in several fields of the sciences and social sciences.

The 'Perspective Shift'

During the last four decades, scientometrics evolved from sub-discipline of information science to an evaluation tool for science policy and research management.

Challenges and present tasks

New challenges force the development of new techniques and methodologies, the exploration and creation of new data sources and the foundation of regional and national research and service centres.

Meso/micro-level
bibliometrics

Ranking

Conclusions

In order to understand the present situation of scientometrics we have to go back to the roots of the field:

- History of science (D. de Solla Price)
- Philosophy (V.V. Nalimov)
- Information science (E. Grafield)
- Sociology of science (R.K. Merton)
- Mathematics (S.D. Haitun, A.I. Yablonsky)

Subject delineation

Bibliometrics and
funding

Meso/micro-level
bibliometrics

Ranking

Conclusions

- Bibliometrics represented a statistical approach to master the growing flood of scientific information and to analyse and to understand the cognitive characteristics of "big science" by measuring quantitative aspects of communication in science and by providing the results to scientists and users outside the scientific community.

Conclusions

In order to take on these challenges, also new centres for science, technology and innovation research have been founded world wide. Nowadays public and commercial institutes are searching for new solutions in bibliometrics and related fields.

Among these institutes, we find research centres with long tradition like ISI (USA), ISSRU (Hungary), VINITI (Russia), CWTS (Netherlands) or NISTADS (India) but also newer ones like OST (France), REPP (Australia), NIFU STEP (Norway), SOOI (Belgium), KAWAX (Chile), WISELAB (China) and IFQ (Germany), the companies Science-Metrix (Canada), Evaluametrics (UK), Evindence (UK) and others.

Conclusions

Scientometrics was designed to measure scholarly communication in basic research. But what happens when information sources and/or targets are outside the community (Glänzel & Schoepflin, 1999)?

Extending bibliometrics to the technical sciences, social sciences and humanities is faced with the following problems.

- Coverage (document type)
- Journal coverage
- National representation
- Language representation
- Role and interpretation of citations
- Quality criteria and comparability

Conclusions

While *Scopus* (Elsevier) evolves to a competitive product to the WoS with similar coverage and similar features, *Google Scholar* is rather a product for the semi-professional user.

The advantage of Google Scholar is its availability and open access, the disadvantage is the lacking documentation and the unclear standards.

At present, none of these databases is able to meet the requirements of present-day research evaluation.

Conclusions

In order to meet the emerging requirements of research evaluation, the possibility of extending existing databases (CWTS, SOOI) or building new, “bibliometric-ready”, databases (e.g., REPP, Australia; NIFU STEP, Norway; VABB-SHW, Flanders) is considered. Some of these databases are already in use.

Different quality criteria, the weight of document types and lacking international harmonisation remain problematic.

Building advanced bibliometric indicators for data extracted from these databases remains an unresolved problem as well. Measures of reception and impact are practically not available.

Conclusions

The lack of appropriate subject-classification schemes for fields, subfields and topics resulted in the following tasks.

- Improving subject delineation and classification based on hybrid methods, i.e., combinations of text mining, and bibliometric techniques (Zitt & Bassecoulrard, 2006, Glänzel et al., 2006, Glenisson et al., 2005, Janssens et al., 2008, 2009, Glänzel et al., 2009)
- Identification of emerging and converging fields, visualisation of structure and field dynamics, domain studies (University of Granada; Information Visualization Lab, Indiana University; Science-Metrix; CWTS, Leiden University; SOOI, KU Leuven; ASCoR, University Amsterdam)

Conclusions

In several studies, “intellectual” subject-classification schemes have been analysed for “goodness” of classification and compared with the results of hybrid clustering.

Example: The 22-field subject classification scheme of the Essential Science Indicators (ESI) is evaluated. In a second step, the hybrid clustering method is applied to classify WoS journals. The choice of 22 clusters also allows a direct field-to-cluster comparison, and we substantiate that the science areas resulting from cluster analysis form a more coherent structure than the “intellectual” reference scheme, the ESI subject scheme. Observed *migration* of journals among science fields can then be adopted to improve classification.

Conclusions

In several countries bibliometric indicators are used as components of funding formulas.

Example: One of the major funding mechanisms for basic science in Flanders is the BOF-mechanism. The *Bijzonder Onderzoeksfonds* is a research fund of the Flemish government that is distributed to the six Flemish universities on the basis of a specific allocation model. This allocation key comprises both input and output measures on the research performance of the universities involved. Part of the key is based on publication and citation data as derived from WoS and ISI Proceedings.

Conclusions

The use of bibliometrics in funding mechanisms might also have undesired consequences, as has reported by Linda Butler.

Example: The publications component of the Composite Index used for allocating university block funding in Australia has stimulated an increased publication activity in the lower impact journals (Butler, 2004).

Conclusions

- Characteristic scores and scales (Glänzel & Schubert, 1988) provide subject-sensitive, self-adjusting thresholds for citation distributions.
- This method can be summarised as iteratively truncating samples at their mean value and recalculating the mean of the truncated sample until the procedure is stopped or the sample is empty.
- $\Rightarrow b_k = E(X|X > b_{k-1})$ with $b_0 := 0$.

Conclusions

- As was shown in earlier studies (e.g., Glänzel, 2007), the scores b_k are *time-dependent* and strongly *sensitive to the subject matter* but the share of papers in the individual zones is relatively stable over the citation window, and does not noticeably vary among different subfields either.
- Characteristic Scores and Scales allow gauging citation impact of any sample (publication output of individual scientists, research groups, departments, institutes, etc.) against a suitable reference standard.

Ranking

Conclusions

Ranking of college and universities, has become one of the most favourite issues in the assessment of higher education institutions and thus one of the new challenges in policy-relevant evaluation.

Since the first edition of the Shanghai Jiao Tong world university ranking and the successor lists, such as the Times Higher Education Supplement - QS World University Rankings, the comparative evaluation of the quality of Education Institutions has been brought into the focus of public and policy interest.

Methodology and discussion is, however, controversial. Even the recently elaborated "Berlin principles" (2006) could not solve the problems. And, as expected, bibliometrics is part of this ranking as well.

In order to clarify the notion of *ranking*, the following comprehensible but nevertheless precise verbal definition is given.

Definition

Ranking is positioning comparable objects on an ordinal scale based on a (non-strict) weak order relation among (statistical) functions of, or a combination of functions of measures or scores associated with those objects.

Remark

These (mainly statistical) functions, which are usually called indicators. Different indicators X_i representing different aspects of quality, form the components of a composite indicator Y , being the basis of the ranking, particularly,

$$Y = \sum \lambda_i X_i,$$

where i ($i = 1, 2, \dots, n$) are n pre-defined weights. Without loss of generality, we can assume that $\sum \lambda_i = 1$.

Meso/micro-level
bibliometrics

Ranking

Conclusions

The most problematic issues in applying composite indicators are as follows.

- The “cleanness” and hence the reliability of underlying data
- The time-variant nature of the underlying data sources
- Possible interdependence of components
- Altering weights can result in different ranking
- Methodology might result in obscure and irreproducible ranking
- Random errors of statistical functions are usually ignored
- The multi-dimensional space is crashed into linearity (loss of information)

Conclusions

In order to account for the complexity of university activities, two basic approaches are possible:

- The *selective ranking* focuses on measuring and ranking according to one selected activity whereas
- the *integrated* or 'holistic' ranking procedure attempts to capture the complex set of all or at least of the most important activities.

The advantages of the first method are obvious as information loss and incommensurability can be reduced and reliability can be increased. In the following we give a concise description of examples for selective and integrated college and university ranking.

Conclusions

In order to account for the complexity of university activities, two basic approaches are possible:

- *Evaluation of education* In 1993 a national education-related university ranking was published in Germany (Spiegel, 1993). The ranking was survey-based. Because of differences and peculiarities of national educational and accreditation systems, such endeavours are practically restricted to the national level.
- *Research performance* With the 'Shanghai Ranking', first published in 2003, the focus was shifted to research assessment. This ranking is largely based on the *Web of Science* and its derivatives.

Meso/micro-level bibliometrics

Ranking

Conclusions

- *'Holistic approach'* The broader approach by THES-QS actually marks a new direction in university ranking, particularly, the trend towards integrated evaluation. It largely relies on peer review score. The holistic approach and a world-wide ranking based on all HEI activities, including education, research and third mission, however, remains at least for the present utopian.

The question arises of whether there is really any need for an integrated ranking.

Meso/micro-level
bibliometrics

Ranking

Conclusions

- Robustness is easily lost by building composite indicators with partially interdependent or incompatible components and arbitrary weights.
- Reality is more complex than can be described this way. Instead of any linear ranking a complex analysis is necessary to capture all aspects of performance among the manifold of a university's activities.
- Bibliometrics can contribute to evaluate at least *one* of these aspects. Standardisation and normalisation help eliminate biases and facilitate longitudinal analysis as well.
- Even normalisation of indicators cannot disguise that comparing HEIs with completely different profiles remains an exercise of 'comparing apples with oranges'.

Conclusions

- Beyond any doubt, growing policy application turned 'little bibliometrics' into 'big bibliometrics'. However, this evolution also resulted in a clear 'perspective shift'.
- The changing shape of scientometrics can be observed world wise. New research and service centres are founded, new journals and conference series are launched. The "geographical" centre of gravity is further shifted towards East.
- This shift, in turn, has severe consequences for the field itself and the whole scientific community as well.
- Bibliometrics is faced with new challenges which have the potential to further transform our field.
